INTRINSIC SCALING FOR PDE’S
WITH AN EXPONENTIAL NONLINEARITY

EURICA HENRIQUES AND JOSÉ MIGUEL URBANO

ABSTRACT: We consider strongly degenerate equations in divergence form of the type
\[ \partial_t u - \nabla \cdot \left( |u|^{\gamma(x,t)} \nabla u \right) = f , \]
where the exponential nonlinearity satisfies the condition \( 0 < \gamma^- \leq \gamma(x,t) \leq \gamma^+ \).
We show, by means of intrinsic scaling, that weak solutions are locally continuous.

KEYWORDS: porous medium equation, degenerate PDE’s, regularity theory, intrinsic scaling.

1. Introduction

Intrinsic scaling has proved to be a remarkably powerful tool in the analysis of the regularity of weak solutions of nonlinear partial differential equations. Devised by DiBenedetto in the early 1980’s, it flourished in the last few years with applications to a wide range of nonlinear equations that exhibit some form of singularity or degeneracy, or both (see, e.g., [5], [6], [8] or [10]).

As many fundamental ideas, intrinsic scaling is strikingly easy to grasp: it amounts to analyze each equation in a geometrical framework related to its structure. The precise understanding of this statement requires a knowledge of the seminal work of DeGiorgi and Moser on regularity theory for uniformly elliptic and parabolic PDE’s with measurable coefficients, namely the iterative methods they developed. These methods consist on a fine analysis of the behaviour of the oscillation for the solutions of the PDE in a sequence of nested and shrinking cylinders, showing that it converges to zero and, when possible, exactly how this happens. The conclusion is that solutions are continuous and, in many instances, that a modulus of continuity can be derived.

In the elliptic case, these results could be extended to equations with the full quasilinear structure but, in the parabolic case, only to equations whose principal part has exactly a linear growth with respect to the modulus of

the gradient of the solution; it appeared that a degeneracy or singularity of the principal part played a peculiar role. The clear understanding of that role had to wait for intrinsic scaling and follows from a single unifying idea: the diffusion processes in the equations evolve in a time scale determined instant by instant by the solution itself, so that, loosely speaking, they can be regarded as the heat equation in their own intrinsic time-configuration. A precise description of this fact, as well as its effectiveness, is closely linked to its technical implementation, namely in terms of the construction of the cylinders in which the iteration process takes place. For a modern account of the theory see [5].

The theory of degenerate and singular elliptic and parabolic equations is one of the branches of modern analysis both in view of the physical significance of the equations at hand and of the novel analytical techniques that they generate. The class of such equations is large, ranging from flows by mean curvature to Monge–Ampère equations to infinity-Laplacian. Parabolic equations in divergence form of the type

$$\partial_t u - \nabla \cdot \left( |u|^{\gamma(x,t)} \nabla u \right) = f \quad \text{in} \quad D'(\Omega_T),$$

with a variable exponent of nonlinearity $\gamma$, are generalizations of the famous porous medium equation and occur as a model for the flow of electro-rheological fluids (cf. [7]). The main feature in equation (1) is clearly the exponential nonlinearity that makes it extremely degenerate. Recently, Antontsev and Shmarev [1] obtained results on the existence and uniqueness of weak solutions of (1), together with some localization properties. Under appropriate assumptions, we prove in this paper that weak solutions are locally continuous. The technique we use is intrinsic scaling.

For the porous medium equation, that corresponds to the case $\gamma \equiv C$, an abundant literature is available. In the case $N > 1$, questions of regularity were first considered by Caffarelli and Friedman in [2]. In more generality, DiBenedetto proved in [3] that weak solutions of

$$\partial_t \beta(u) - \nabla \cdot a(x, t, u, \nabla u) = b(x, t, u, \nabla u),$$

where $\beta(s) = |s|^{\frac{1}{m}} \text{sign} s$, $m > 1$, are locally continuous imposing no restrictions on the sign of $u$ nor any relationship between the (possibly nonlinear) $a(x, t, u, \nabla u), b(x, t, u, \nabla u)$ and the graph $\beta$. Other generalizations, to equations with a double degeneracy, were considered in [8] and [10].
2. The equation in its own geometry

Consider the equation
\[
\partial_t u - \nabla \cdot \left( |u|^\gamma(x,t) \nabla u \right) = 0 \quad \text{in} \quad D'(\Omega_T)
\] (2)

where \( \Omega_T = \Omega \times (0, T] \), \( \Omega \) is a regular bounded domain in \( \mathbb{R}^N \), and \( 0 < T < \infty \). We assume the exponent \( \gamma \) satisfies the following assumptions:

(A1) \( \gamma \in L^\infty \left( 0, T; W^{1,\infty} (\Omega) \right) \), with \( \| \gamma \|_{L^\infty(0,T;W^{1,\infty}(\Omega))} = M \);

(A2) For constants \( \gamma^- > 0, \gamma^+ > 0 \),
\[
0 < \gamma^- \leq \gamma(x,t) \leq \gamma^+ < \infty , \quad \text{a.e.} \ (x,t) \in \Omega_T .
\]

Definition 1. We say that a measurable function \( u \) is a local weak solution of (2) if

- \( u \in L^\infty (0, T; L^\infty(\Omega)) \) with \( u(x,t) \in [0, 1] \) a.e. in \( \Omega_T \);
- \( u \in C \left( 0, T; L^2(\Omega) \right) \) and \( u^{\gamma(x,t)} \nabla u \in L^2 \left( 0, T; L^2(\Omega) \right) \);
- for every compact \( K \subset \Omega \) and for every subinterval \( [t_1, t_2] \subset (0, T] \),
\[
\int_K u \phi \, dx \bigg|_{t_1}^{t_2} + \int_{t_1}^{t_2} \int_K \left\{ -u \partial_t \phi + u^{\gamma(x,t)} \nabla u \cdot \nabla \phi \right\} \, dx \, dt = 0 , \quad (3)
\]
for all functions \( \phi \in H^1_{\text{loc}} \left( 0, T; L^2(K) \right) \cap L^2_{\text{loc}} \left( 0, T; H^1_0(K) \right) \).

It is convenient to our purposes to have at hand a definition of weak solution involving a discrete time derivative. Making use of the Steklov average of a function (see [4] for more details) we obtain the following formulation which is equivalent to (3):

- for every compact \( K \subset \Omega \) and for all \( 0 < t < T - h \),
\[
\int_{K \times \{t\}} \partial_t u_h \phi \, dx + \int_{K \times \{t\}} \left( u^{\gamma(x,r)} \nabla u \right)_h \cdot \nabla \phi \, dx = 0 , \quad (4)
\]
for all \( \phi \in H^1_0(K) \).

In the recent paper [1], it is proved, under less restrictive assumptions on \( \gamma \), that there exists a unique solution to the initial boundary value problem associated with this equation and that the solution is bounded. It is also shown that the solution is nonnegative if the initial data is nonnegative; that
is why the assumption \( u(x, t) \in [0, 1] \text{ a.e. in } \Omega_T \) included in Definition 1 is reasonable.

Observe that the equation is degenerate at points where \( u = 0 \), since for \( \gamma \) verifying (A2), the diffusion coefficient \( u^\gamma(x, t) \) vanishes at those points. To deal with this fact we need to define an intrinsic geometric configuration for this specific PDE. We start with some notation. Given \( x_0 \in \mathbb{R}^N \), define the \( N \)-dimensional cube

\[
[x_0 + K_\rho] := \left\{ x : \max_{1 \leq i \leq N} |x_i - x_{0i}| < \rho \right\}.
\]

Given the pair \((x_0, t_0)\) \(\in \mathbb{R}^{N+1}\), define the cylinder

\[
[(x_0, t_0) + Q(\tau, \rho)] := [x_0 + K_\rho] \times (t_0 - \tau, t_0).
\]

Now, let \((x_0, t_0)\) be a point of the space-time domain \(\Omega_T\) that, by translation, we may assume to be \((0,0)\). Consider small positive numbers \(\epsilon > 0\) and \(R > 0\) such that the cylinder \(Q(R^{2-\epsilon}, R) \subset \Omega_T\) and define

\[
\mu^- := \operatorname{ess \ inf}_{Q(R^{2-\epsilon}, R)} u ; \quad \mu^+ := \operatorname{ess \ sup}_{Q(R^{2-\epsilon}, R)} u ; \quad \omega := \operatorname{ess \ osc}_{Q(R^{2-\epsilon}, R)} u = \mu^+ - \mu^-.
\]

Recalling that (2) is degenerate at the points where \( u = 0 \), the interesting case to investigate is when \( \mu^- = 0 \) and, consequently, \( \mu^+ = \omega \). From now on, we will assume this is in force.

Construct the cylinder

\[
Q(a_0 R^2, R) , \quad a_0 = \left( \frac{4}{\omega} \right)^{\gamma^+},
\]

and assume that

\[
\omega \geq 4 R^{\gamma^+}.
\]

This implies that \(Q(a_0 R^2, R) \subset Q(R^{2-\epsilon}, R)\) and then

\[
\operatorname{ess \ osc}_{Q(a_0 R^2, R)} u \leq \omega.
\]

For technical reasons, we make the extra assumption that \(\epsilon \leq 2 \gamma^+\).

**Remark 1.** If (5) does not hold, then the oscillation \( \omega \) goes to zero when the radius \( R \) goes to zero, in a way given by the reverse inequality, and there is nothing to prove. Note that, in general, (6) is not verified a priori for a given cylinder. The cylinder dimensions had to be defined in terms of the oscillation of the solution within it.
When $\gamma \equiv 0$, $a_0 = 1$ and we recover the standard parabolic cylinder with the natural homogeneity of the space and time variables.

The proof of the main result of this paper relies on the study of two complementary cases that can be described as follows: either $u$ is essentially away from its infimum in the constructed cylinder, or this does not hold. In either case, we are able to reduce the oscillation of $u$ within a smaller cylinder with the same "vertex". The alternative can be formulated as

Given $\nu_0 \in (0, 1)$, to be determined in terms of the data and $\omega$, either

$$\left| (x, t) \in Q(a_0 R^2, R) : u(x, t) < \frac{\omega}{2} \right| \leq \nu_0 \left| Q(a_0 R^2, R) \right| \quad (7)$$

or, noting that $\mu^+ - \frac{\omega}{2} = \frac{\omega}{2}$,

$$\left| (x, t) \in Q(a_0 R^2, R) : u(x, t) > \mu^+ - \frac{\omega}{2} \right| < (1 - \nu_0) \left| Q(a_0 R^2, R) \right| . \quad (8)$$

The analysis of this alternative leads to the following result.

**Proposition 1.** There exist positive numbers $\nu_0, \sigma \in (0, 1)$, depending on the data and on $\omega$, such that

$$\text{ess osc}_{Q\left(\frac{\nu_0 a_0}{2}, \frac{R}{2}, \frac{R}{2}\right)} u \leq \sigma \omega . \quad (9)$$

An immediate consequence is

**Theorem 1.** Under assumptions $(A1) - (A2)$ any locally bounded weak solution of (2) is locally continuous in $\Omega_T$.

The proof of Theorem 1 is a (now standard) consequence of Proposition 1. Indeed, from (9) one can recursively define a sequence $Q_n$ of nested and shrinking cylinders and a sequence $\omega_n$ converging to zero, such that

$$\text{ess osc}_{Q_n} u \leq \omega_n .$$

Continuity of $u$ follows. For a proof of these facts, the reader is invited to read the survey paper [5].
Remark 2. We stress that we only obtain continuity of $u$, and are unable to derive a modulus, since the constant $\sigma$ appearing in Proposition 1 depends on the oscillation $\omega$. See [9] for the details.

3. Reducing the oscillation

Assume that (7) is verified. In the following, we determine the number $\nu_0$ and guarantee that the solution $u$ is above a smaller level within a smaller cylinder.

Proposition 2. There exists $\nu_0 \in (0, 1)$, depending only on the data and $\omega$, such that if (7) holds true then

$$u(x, t) \geq \frac{\omega}{4}, \quad \text{a.e.} \ (x, t) \in Q \left( a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2} \right). \quad (10)$$

Proof. Define two decreasing sequences of positive numbers

$$R_n = \frac{R}{2} + \frac{R}{2^{n+1}}, \quad k_n = \frac{\omega}{4} + \frac{\omega}{2^{n+2}}, \quad n = 0, 1, \ldots$$

and construct the family of nested and shrinking cylinders $Q_n = Q(a_0 R_n^2, R_n)$. Introduce the function $u_\omega = \max \{u, \frac{\omega}{4}\}$. In the weak formulation (4) take $\phi = -((u_\omega)_h - k_n)_- \xi_n^2$, where $0 \leq \xi_n \leq 1$ are smooth cutoff functions defined in $Q_n$ and satisfying

$$\begin{cases} 
\xi_n \equiv 1 \quad \text{in} \ Q_{n+1}, \\
\xi_n \equiv 0 \quad \text{on the parabolic boundary of} \ Q_n \\
|\nabla \xi_n| \leq \frac{2^{n+2}}{R}, \quad |\Delta \xi_n| \leq \frac{2^{2(n+2)}}{R^2}, \quad 0 < \partial_t \xi_n \leq \frac{2^{2(n+2)}}{a_0 R^2},
\end{cases}$$

and integrate in time over $(-a_0 R_n^2, t)$, for $t \in (-a_0 R_n^2, 0)$. We obtain (omitting the $dx$ and $dt$ in all integrals from now on)

$$I_1 + I_2 := \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \partial_t u_h \left[ -((u_\omega)_h - k_n)_- \xi_n^2 \right]$$

$$+ \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} (u^\gamma \nabla u)_h \cdot \nabla \left[ -((u_\omega)_h - k_n)_- \xi_n^2 \right] = 0.$$
\[ + \int_{t-a_0 R_n^2}^t \int_{K_{R_n}} \partial_t u_h \left[ - \left( (u_\omega)_h - k_n \right)_- \xi_n^2 \right] \chi_{[(u_\omega)_h=\frac{\omega}{4}]} \]

\[ = \frac{1}{2} \int_{t-a_0 R_n^2}^t \int_{K_{R_n}} \partial_t \left[ \left( (u_\omega)_h - k_n \right)_- \right] \xi_n^2 \]

\[ + \left( \frac{\omega}{2n+2} \right) \int_{t-a_0 R_n^2}^t \int_{K_{R_n}} \partial_t \left[ \left( u_h - \frac{\omega}{4} \right)_- \right] \xi_n^2 . \]

Next, we integrate by parts and let \( h \to 0 \). Using Lemma 3.2 of Chapter I of [4] we get

\[ \frac{1}{2} \int_{K_{R_n} \times \{t\}} (u_\omega - k_n)^2 \xi_n^2 - \int_{-a_0 R_n^2}^t \int_{K_{R_n}} (u_\omega - k_n)^2 \xi_n \partial_t \xi_n \]

\[ + \left( \frac{\omega}{2n+2} \right) \int_{K_{R_n} \times \{t\}} (u - \frac{\omega}{4})^2 \xi_n^2 - 2 \left( \frac{\omega}{2n+2} \right) \int_{-a_0 R_n^2}^t \int_{K_{R_n}} (u - \frac{\omega}{4})^2 \xi_n \partial_t \xi_n \]

\[ \geq \frac{1}{2} \int_{K_{R_n} \times \{t\}} (u_\omega - k_n)^2 \xi_n^2 - 3 \left( \frac{\omega}{4} \right)^2 \frac{2^{2(n+2)} a_0 R_n^2}{a_0 R_n^2} \int_{-a_0 R_n^2}^t \int_{K_{R_n}} \chi_{[u_\omega \leq k_n]} , \]

since the third term is nonnegative and, for \( 0 \leq u \leq \frac{\omega}{4} \),

\[ u_\omega = \frac{\omega}{4} \leq k_n \]

and, for \( \frac{\omega}{4} < u = u_\omega \leq k_n \),

\[ (u_\omega - k_n)_- \leq k_n - u_\omega = k_n - u < k_n - \frac{\omega}{4} = \frac{\omega}{2n+2} \leq \frac{\omega}{4} . \]

Concerning \( I_2 \), we first pass to the limit in \( h \) to get

\[ I_2 \to \int_{-a_0 R_n^2}^t \int_{K_{R_n}} u_\gamma \nabla u \cdot \nabla \left( - (u_\omega - k_n)_- \xi_n^2 \right) \]

\[ = \int_{-a_0 R_n^2}^t \int_{K_{R_n}} u_\gamma \nabla u \cdot \nabla \left( - (u_\omega - k_n)_- \xi_n^2 \right) \chi_{[u_\omega = u]} \]

\[ + \int_{-a_0 R_n^2}^t \int_{K_{R_n}} u_\gamma \nabla u \cdot \nabla \left( - (u_\omega - k_n)_- \xi_n^2 \right) \chi_{[u_\omega = \frac{\omega}{4}]} \]

\[ = \int_{-a_0 R_n^2}^t \int_{K_{R_n}} u_\gamma |\nabla (u_\omega - k_n)_-|^2 \xi_n^2 . \]
\[ +2 \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} u_\omega \nabla (u_\omega - k_n)_- \cdot \nabla \xi_n \xi_n (u_\omega - k_n)_- \]

\[ +2 \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} -u_\gamma \nabla u \cdot \nabla \xi_n \xi_n \chi_{[u \leq \frac{\omega}{4}]} \]

\[ \geq \frac{1}{2} \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} u_\omega \nabla (u_\omega - k_n)_-^2 \xi_n^2 \]

\[ -2 \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} u_\omega \nabla \xi_n^2 (u_\omega - k_n)_-^2 \]

\[ +2 \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \nabla \left( \int_{u}^{\frac{\omega}{4}} s^\gamma \ ds \right) \cdot \nabla \xi_n \xi_n \chi_{[u \leq \frac{\omega}{4}]} \]

\[ +2 \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{u}^{\frac{\omega}{4}} (-\ln s)s^\gamma \ ds \right) \nabla \gamma \cdot \nabla \xi_n \xi_n \chi_{[u \leq \frac{\omega}{4}]} \]

\[ \geq \frac{1}{2} \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} u_\omega \nabla (u_\omega - k_n)_-^2 \xi_n^2 \]

\[ -2 \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} u_\omega \nabla \xi_n^2 (u_\omega - k_n)_-^2 \]

\[ -2 \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{u}^{\frac{\omega}{4}} s^\gamma \ ds \right) \left( \xi_n | \Delta \xi_n | + | \nabla \xi_n |^2 \right) \chi_{[u \leq \frac{\omega}{4}]} \]

\[ - \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{u}^{\frac{\omega}{4}} (-\ln s)s^\gamma \ ds \right) | \nabla \gamma |^2 \xi_n \chi_{[u \leq \frac{\omega}{4}]} \]

\[ - \left( \frac{\omega}{2^{n+2}} \right) \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{u}^{\frac{\omega}{4}} (-\ln s)s^\gamma \ ds \right) | \nabla \xi_n |^2 \xi_n \chi_{[u \leq \frac{\omega}{4}]} \]

\[ =: I_2'. \]

The first inequality is obtained by means of Cauchy’s inequality with \( \epsilon = \frac{1}{4} \), and the observation that, within the set \([u \leq \frac{\omega}{4}]\),

\[ \nabla \left( \int_{u}^{\frac{\omega}{4}} s^\gamma \ ds \right) = -u^\gamma \nabla u - \left( \int_{u}^{\frac{\omega}{4}} (-\ln s)s^\gamma \ ds \right) \nabla \gamma \ .\]

The second inequality is a consequence of integration by parts and again Cauchy’s inequality, this time with \( \epsilon = \frac{1}{2} \).
Next, observe that for $\omega^4 < u = u_\omega \leq k_n$, we get

$$\frac{1}{a_0} \leq \left(\frac{\omega}{4}\right)^\gamma < u_\omega \leq 1 \quad \text{using } (A2),$$

and for $u \leq \frac{\omega}{4}$, we get

$$u_\omega = \frac{\omega}{4} \leq k_n;$$

$$\int_u^{\frac{\omega}{4}} s^{\gamma} \, ds \leq \left(\frac{\omega}{4}\right)^\gamma \left(\frac{\omega}{4} - u\right) \leq \frac{\omega}{4};$$

$$\int_u^{\frac{\omega}{4}} (-\ln s) s^{\gamma} \, ds \leq \left(\frac{\omega}{4}\right)^\gamma \int_u^{\frac{\omega}{4}} (-\ln s) \, ds \leq \int_u^{\frac{\omega}{4}} (-\ln s) \, ds = -\frac{\omega}{4} \ln \left(\frac{\omega}{4}\right) + u \ln u + \frac{\omega}{4} - u \leq \left(\frac{\omega}{4} - u\right) \left\{\ln \left(\frac{4}{\omega}\right) + 1\right\} \leq \left(\frac{\omega}{4}\right) \frac{4}{\omega} = 1.$$  

Using these inequalities, recalling the conditions on $\xi_n$, the fact that $\omega \leq 1$, and the following consequence of $(5)$ and the choice $\epsilon \leq 2\gamma^+$

$$\frac{1}{R^2} \geq \frac{\omega^4}{R^{\gamma^+}} \geq 1,$$

$I'_2$ is bounded from below by

$$\frac{1}{2a_0} \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} |\nabla (u_\omega - k_n) - \xi_n|^2 \, \xi_n^2 \, \chi[u_\omega \leq k_n].$$

Combining the above results, we obtain the energy estimates

$$\sup_{-a_0 R_n^2 < t < 0} \int_{K_{R_n} \times \{t\}} (u_\omega - k_n)^2 \xi_n^2 + \frac{1}{a_0} \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} |\nabla (u_\omega - k_n) - \xi_n|^2 \, \xi_n^2 \chi[u_\omega \leq k_n] \leq 6 \left(\frac{\omega}{4}\right)^2 2^{2(n+2)} a_0 R_n^2 \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \chi[u_\omega \leq k_n]$$

$$+ \frac{C(M)}{\omega} \left(\frac{\omega}{4}\right)^2 2^{2(n+2)} R_n^2 \int_{-a_0 R_n^2}^{t} \int_{K_{R_n}} \chi[u_\omega \leq k_n].$$
Let us now consider the change of variables

\[ z = \frac{t}{a_0} \]

and define the new functions

\[ \bar{u}_\omega(x, z) = u_\omega(x, a_0 z) \quad ; \quad \bar{\xi}_n(x, z) = \xi_n(x, a_0 z) . \]

Then the above estimates read

\[
\sup_{-R_n^2 < z < 0} \int_{K_{R_n} \times \{z\}} (\bar{u}_\omega - k_n)^2 \bar{\xi}_n^2 + \int_{-R_n^2}^0 \int_{K_{R_n}} |\nabla (\bar{u}_\omega - k_n) - \bar{\xi}_n|^2 \]

\[
\leq 6 \left( \frac{\omega}{4} \right)^2 \frac{2^{2(n+2)}}{R^2} \int_{-R_n^2}^0 \int_{K_{R_n}} \chi[\bar{u}_\omega \leq k_n]
+ \frac{C(M, \gamma^+)}{\omega^{1+\gamma^+}} \left( \frac{\omega}{4} \right)^2 \frac{2^{2(n+2)}}{R^2} \int_{-R_n^2}^0 \int_{K_{R_n}} \chi[\bar{u}_\omega \leq k_n]
\]

\[
\leq \frac{C(M, \gamma^+)}{\omega^{1+\gamma^+}} \left( \frac{\omega}{4} \right)^2 \frac{2^{2(n+2)}}{R^2} A_n ,
\]

for \( A_n \equiv \int_{-R_n^2}^0 \int_{K_{R_n}} \chi[\bar{u}_\omega \leq k_n] \). These estimates imply the inequality

\[
\| (\bar{u}_\omega - k_n) - \|_{V^2(Q(R_{n+1}^2, R_{n+1}))}^2 \leq \frac{C(M, \gamma^+)}{\omega^{1+\gamma^+}} \left( \frac{\omega}{4} \right)^2 \frac{2^{2(n+2)}}{R^2} A_n ,
\]

where \( V^2 = L^\infty(L^2) \cap L^2(H^1) \). Using Corollary 3.1 of [4, page 9], we get

\[
\left( \frac{\omega}{4} \right)^2 \frac{1}{2^{2(n+1)}} A_{n+1} = (k_n - k_{n+1})^2 A_{n+1} \leq \int \int_{Q(R_{n+1}^2, R_{n+1})} (\bar{u}_\omega - k_n)^2
\]

\[
\leq C(N) \left| [\bar{u}_\omega \leq k_n] \cap Q(R_{n+1}^2, R_{n+1}) \right|^{\frac{2}{n+2}} \| (\bar{u} - k_n) - \|_{V^2(Q(R_{n+1}^2, R_{n+1}))}^2
\]

\[
\leq C(N) A_n^{\frac{2}{n+2}} \| (\bar{u} - k_n) - \|_{V^2(Q(R_{n+1}^2, R_{n+1}))}^2 ,
\]

and consequently

\[
A_{n+1} \leq \frac{C(M, N, \gamma^+)}{\omega^{1+\gamma^+}} \frac{2^{4n}}{R^2} A_n^{1+\frac{2}{n+2}} .
\]
Defining \( Y_n \equiv \frac{A_n}{|Q(R^2_n, R_n)|} \) and noting that \( \frac{|Q(R^2_n, R_n)|}{|Q(R^2_{n+1}, R_{n+1})|} \leq 2^{N+4}R^2 \), we arrive at the algebraic inequality

\[
Y_{n+1} \leq \frac{C(M, N, \gamma^+)}{\omega^{1+\gamma^+}} 2^{4n} Y_n^{1+\frac{2}{N+2}}.
\]

Now, by Lemma 4.1 of [4, page 12], if

\[
Y_0 \leq C(M, N, \gamma^+) - \frac{N+2}{2} 2^{-(N+2)} \omega^{(1+\gamma^+)\frac{N+2}{2}}
\]

then \( Y_n \to 0 \) as \( n \to \infty \). Taking

\[
\nu_0 \equiv \frac{C(M, N, \gamma^+)}{\omega^{1+\gamma^+}} 2^{-(N+2)} \omega^{(1+\gamma^+)\frac{N+2}{2}}
\]

the above inequality is valid since it is no other than our hypothesis. Since \( R_n \searrow \frac{R}{2}, k_n \searrow \frac{\omega}{4} \), and \( Y_n \to 0 \) as \( n \to \infty \) implies that \( A_n \to 0 \) as \( n \to \infty \), we obtain

\[
(x, z) \in Q \left( \left( \frac{R}{2} \right)^2, \frac{R}{2} \right) : \bar{u}_\omega(x, z) \leq \frac{\omega}{4} = 0,
\]

that is,

\[
u_0 \equiv \frac{C(M, N, \gamma^+)}{\omega^{1+\gamma^+}} 2^{-(N+2)} \omega^{(1+\gamma^+)\frac{N+2}{2}} = 0.
\]

The reduction of the oscillation of \( u \) follows at once. Indeed, we have

**Corollary 1.** There exist constants \( \nu_0 \in (0, 1) \), depending on the data and \( \omega \), and \( \sigma_0 \in (0, 1) \), such that if (7) holds then

\[
\text{ess osc}_{Q(a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2})} u \leq \sigma_0 \omega.
\]

**Proof.** From Proposition 2 we know that

\[
\text{ess inf}_{Q(a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2})} u(x, t) \geq \frac{\omega}{4}.
\]

Thereby, since \( \mu^+ \geq \text{ess sup}_{Q(a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2})} u \),

\[
\text{ess osc}_{Q(a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2})} u \leq \mu^+ - \frac{\omega}{4} = \left( 1 - \frac{1}{4} \right) \omega \equiv \sigma_0 \omega.
\]
4. The alternative

Now we assume that (7) does not hold, so therefore (8) is in force. We will show that, in this case, we can get a result similar to (12). Remember that $\nu_0$ was already determined and is given by (11).

Lemma 1. Assume that (8) holds true. There exists a time level

$$t_0 \in \left[-a_0 R^2, -\frac{\nu_0}{2} a_0 R^2\right]$$

such that

$$|x \in K_R : u(x, t_0) > \mu^+ - \frac{\omega}{2}| < \left(\frac{1 - \nu_0}{1 - \frac{\nu_0}{2}}\right) |K_R| \ .$$

Proof. In fact, if not then

$$\left|(x, t) \in Q \left(a_0 R^2, R\right) : u(x, t) > \mu^+ - \frac{\omega}{2}\right|$$

$$\geq \int_{-a_0 R^2}^{-\frac{\nu_0}{2} a_0 R^2} |x \in K_R : u(x, t) > \mu^+ - \frac{\omega}{2}| \ dt$$

$$\geq \left(\frac{1 - \nu_0}{1 - \frac{\nu_0}{2}}\right) |K_R| \left(1 - \frac{\nu_0}{2}\right) a_0 R^2$$

$$= (1 - \nu_0) \left|Q \left(a_0 R^2, R\right)\right|$$

contradicting (8).

Accordingly, at time level $t_0$, the portion of the cube $K_R$ where $u(x)$ is close to its supremum is small. In what follows we will show that the same happens for all time levels near the top of the cylinder $Q \left(a_0 R^2, R\right)$.

Lemma 2. There exists $1 < s_1 \in \mathbb{N}$, depending on the data and $\omega$, such that, for all $t \in (t_0, 0)$,

$$|x \in K_R : u(x, t) > \mu^+ - \frac{\omega}{2^{s_1}}| < \left(1 - \left(\frac{\nu_0}{2}\right)^2\right) |K_R| .$$

Proof. Consider the cylinder $Q \left(t_0, R\right)$ and the level $k = \mu^+ - \frac{\omega}{2}$. Define

$$u - k \leq H_k^+ \equiv \text{ess sup}_{Q(t_0, R)} (u - k)_+ \leq \frac{\omega}{2} ,$$
which we assume to be strictly positive (otherwise there will be nothing to prove). Select \( n_\ast \in \mathbb{N} \) big enough so that \( 0 < c = \frac{\omega}{2n_\ast + 1} < H_k^+ \). Then the logarithmic function \( \psi^+ \) given by
\[
\psi^+ = \begin{cases} 
\ln \left( \frac{H_k^+}{H_k^+-u+k+c} \right) & \text{if } u > k + c \\
0 & \text{if } u \leq k + c 
\end{cases}
\]
is well defined and satisfies the inequalities
\[
\psi^+ \leq \ln(2^{n_\ast}) = n_\ast \ln 2 , \quad \text{since} \quad \frac{H_k^+}{H_k^+-u+k+c} \leq \frac{H_k^+}{c} \leq \frac{\omega}{\omega / 2n_\ast + 1} = 2^{n_\ast}
\]
and, for \( u \neq k + c \),
\[
0 \leq (\psi^+)' \leq \frac{1}{H_k^+-u+k+c} \leq \frac{1}{c} = \frac{2^{n_\ast+1}}{\omega}
\]
and
\[
(\psi^+)^{\prime\prime} = \left[(\psi^+)^{\prime}\right]^2 \geq 0 .
\]

In the weak formulation (3) [to be rigorous we should consider, as before, formulation (4), integrate and take the limit as \( h \to 0 \); to simplify we proceed formally at this stage] consider the integration over \( K_R \times (t_0, t) \), with \( t \in (t_0, 0) \), and take \( \phi = 2\psi^+ (\psi^+)^{\prime} \xi^2 \), where \( x \to \xi(x) \) is a smooth cutoff function defined in \( K_R \) and verifying
\[
\begin{cases}
0 \leq \xi \leq 1 & \text{in } K_R ; \\
\xi \equiv 1 & \text{in } K_{(1-\sigma)R} , \text{ for some } \sigma \in (0, 1) ; \\
|\nabla \xi| \leq \frac{C}{\sigma R} .
\end{cases}
\]
Then, for all \( t \in (t_0, 0) \),
\[
0 = \int_{t_0}^{t} \int_{K_R} \partial_t u \left(2\psi^+ (\psi^+)^{\prime} \xi^2\right) + \int_{t_0}^{t} \int_{K_R} u^\gamma(x,t) \nabla u \cdot \nabla \left(2\psi^+ (\psi^+)^{\prime} \xi^2\right) \\
=: J_1 + J_2 .
\]
The two integrals can the estimated as follows:
\[
J_1 = \int_{K_R \times \{t\}} (\psi^+)^2 \xi^2 - \int_{K_R \times \{t_0\}} (\psi^+)^2 \xi^2
\]
\[ \geq \int_{K_R \times \{t\}} (\psi^+)^2 \xi^2 - n_\ast^2 \ln^2 2 \left( \frac{1 - \nu_0}{1 - \frac{\nu_0}{2}} \right) |K_R|, \]

using the estimate for \( \psi^+ \) and Lemma 1;

\[ J_2 = \int_{t_0}^t \int_{K_R} u^{\gamma(t)} |\nabla u|^2 \left( 1 + \psi^+ \right) \left[ (\psi^+) \right]^2 \xi^2 \]

\[ + 2 \int_{t_0}^t \int_{K_R} u^{\gamma(x,t)} \nabla u \cdot \nabla \xi (2 \psi^+) \xi \]

\[ \geq - \int_{t_0}^t \int_{K_R} u^{\gamma(x,t)} |\nabla \xi| 2 \psi^+, \]

using Cauchy’s inequality. Putting these estimates together, using the bounds for \( |\nabla \xi| \) and \( \psi^+ \), and recalling what \( t_0 \) and \( a_0 \) are, we arrive at

\[ \int_{K_R \times \{t\}} (\psi^+)^2 \xi^2 \leq \left[ n_\ast^2 \ln^2 2 \left( \frac{1 - \nu_0}{1 - \frac{\nu_0}{2}} \right) + 2n_\ast \ln 2 \frac{C}{\sigma^2 R^2} (-t_0) \right] |K_R| \]

\[ \leq \left[ n_\ast^2 \ln^2 2 \left( \frac{1 - \nu_0}{1 - \frac{\nu_0}{2}} \right) + 2n_\ast \ln 2 \frac{C}{\sigma^2 a_0} \right] |K_R| \]

\[ \leq \left[ n_\ast^2 \ln^2 2 \left( \frac{1 - \nu_0}{1 - \frac{\nu_0}{2}} \right) + 2n_\ast \ln 2 \frac{C(\gamma^+)}{\sigma^2 \omega^\gamma^+} \right] |K_R|, \]

valid for all \( t \in (t_0, 0) \).

The left hand side is estimated from below considering integration over the smaller set

\[ S = \left\{ x \in K_{(1-\sigma)R} : u(x,t) > \mu^+ - \frac{\omega}{2^{n_\ast+1}} \right\}. \]

On \( S \), \( \xi \equiv 1 \) and \( \psi^+ \geq (n_\ast - 1) \ln 2 \), because

\[ \frac{H_k^+}{H_k^+ - u + k + c} \geq \frac{H_k^+}{H_k^+ - \frac{\omega}{2} + \frac{\omega}{2^{n_\ast}}} = \frac{H_k^+ - \frac{\omega}{2} + \frac{\omega}{2^{n_\ast}}}{H_k^+ - \frac{\omega}{2} + \frac{\omega}{2^{n_\ast}}} \geq 2^{n_\ast-1}, \]

since one has \( H_k^+ - \frac{\omega}{2} \leq 0 \) and \( \frac{\omega}{2^{n_\ast}} > \frac{\omega}{2^{n_\ast}}, \forall n_\ast > 1 \). Therefore, for all \( t \in (t_0, 0) \),

\[ |S| \leq \left\{ \left( \frac{n_\ast}{n_\ast - 1} \right)^2 \left( \frac{1 - \nu_0}{1 - \frac{\nu_0}{2}} \right) + \frac{C}{\sigma^2 n_\ast \omega^\gamma^+} \right\} |K_R|. \]

Consequently, for all \( t \in (t_0, 0) \),

\[ \left| x \in K_R : u(x,t) > \mu^+ - \frac{\omega}{2^{n_\ast+1}} \right| \leq |S| + N \sigma |K_R|. \]
\[
\leq \left\{ \left( \frac{n_*}{n_* - 1} \right)^2 \left( 1 - \frac{\nu_0}{2} \right) + \frac{C}{\sigma^2 n_* \omega^\gamma} + N \sigma \right\} |K_R|.
\]

The proof is complete once we choose \( \sigma \) so small that \( N \sigma \leq \frac{3}{8} \nu_0^2 \), then \( n_* \) so large that
\[
\frac{C}{n_* \sigma^2 \omega^\gamma} \leq \frac{3}{8} \nu_0^2 \quad \text{and} \quad \left( \frac{n_*}{n_* - 1} \right)^2 \leq \left( 1 - \frac{\nu_0}{2} \right) (1 + \nu_0) \equiv \beta > 1,
\]
and finally take \( s_1 = n_* + 1 \). \qed

\textbf{Remark 3.} Note that, from the choice of \( \sigma \), we get \( \sigma < \frac{3}{8N \nu_0^2} \) and from the two conditions on \( n_* \) we obtain
\[
n_* \geq \max \left\{ C \nu_0^{-6} \omega^{-\gamma} ; \frac{4}{\nu_0^2} + 2 \right\}.
\]

Clearly the number \( s_1 \) depends on the data as well as on \( \omega \).

Recalling that \( t_0 \in [-a_0 R^2, -\frac{\omega}{2} a_0 R^2] \), the previous lemma implies

\textbf{Corollary 2.} There exists \( 1 < s_1 \in \mathbb{N} \), depending on the data and \( \omega \), such that, for all \( t \in (-\frac{\omega}{2} a_0 R^2, 0) \),
\[
|x \in K_R : u(x,t) > \mu^+ - \frac{\omega}{2^{s_1}}| < \left( 1 - \left( \frac{\nu_0}{2} \right)^2 \right) |K_R|.
\]

The conclusion of Corollary 2 will be employed to deduce that, within the cylinder \( Q \left( \frac{\nu_0}{2} a_0 R^2, R \right) \), the set where \( u \) is close to its supremum is arbitrarily small.

\textbf{Lemma 3.} For all \( \nu \in (0,1) \) there exists \( s_1 < s_2 \in \mathbb{N} \), depending on the data and \( \omega \), such that
\[
| (x,t) \in Q \left( \frac{\nu_0}{2} a_0 R^2, R \right) : u(x,t) > \mu^+ - \frac{\omega}{2^{s_2}} | \leq \nu \quad |Q \left( \frac{\nu_0}{2} a_0 R^2, R \right)|.
\]

\textbf{Proof.} Consider the cylinder \( Q \left( \nu_0 a_0 R^2, 2R \right) \) and the levels \( k = \mu^+ - \frac{\omega}{2^s} \), for \( s \geq s_1 \). In order to obtain energy estimates for the functions \((u-k)_+\) over
this cylinder, in (3) we take \( \phi = (u - k)_+ \xi^2 \), where \( 0 \leq \xi \leq 1 \) is a smooth cutoff function defined in \( Q (\nu_0a_0R^2, 2R) \) and satisfying

\[
\begin{cases}
\xi \equiv 0 & \text{on } \partial_p Q (\nu_0a_0R^2, 2R) ; \\
\xi \equiv 1 & \text{in } Q (\frac{\nu_0}{2}a_0R^2, R) ; \\
|\nabla \xi| \leq \frac{1}{R}; & 0 \leq \partial_t \xi \leq \frac{1}{\nu_0a_0R^2},
\end{cases}
\]

where \( \partial_p Q (\nu_0a_0R^2, 2R) \) denotes the parabolic boundary of \( Q (\nu_0a_0R^2, 2R) \). Then, for \( t \in (-\nu_0a_0R^2, 0) \), we obtain (again formally)

\[
\int_{-\nu_0a_0R^2}^t \int_{K_{2R}} \partial_t u (u - k)_+ \xi^2 + \int_{-\nu_0a_0R^2}^t \int_{K_{2R}} u^{\gamma(x,t)} \nabla u \cdot \nabla ((u - k)_+ \xi^2) = 0 .
\]

Now, since \( (u - k)_+ \leq \frac{\omega}{2} \),

\[
\int_{-\nu_0a_0R^2}^t \int_{K_{2R}} \partial_t u (u - k)_+ \xi^2 = \frac{1}{2} \int_{K_{2R} \times \{t\}} (u - k)_+^2 \xi^2 - \int_{-\nu_0a_0R^2}^t \int_{K_{2R}} (u - k)_+^2 \xi \partial_t \xi \\
\geq - \left( \frac{\omega}{2s} \right)^2 \frac{1}{\nu_0^2 a_0 R^2} \int_{-\nu_0a_0R^2}^t \int_{K_{2R}} \chi_{[u>k]}
\]

and

\[
\int_{-\nu_0a_0R^2}^t \int_{K_{2R}} u^{\gamma(x,t)} \nabla u \cdot \nabla ((u - k)_+^2) \\
\geq \frac{1}{2a_0} \int_{-\nu_0a_0R^2}^t \int_{K_{2R}} |\nabla (u - k)_+|^2 \xi^2 - 2 \left( \frac{\omega}{2s} \right)^2 \frac{1}{R^2} \int_{-\nu_0a_0R^2}^t \int_{K_{2R}} \chi_{[u>k]} ,
\]

using Cauchy’s inequality with \( \epsilon = \frac{1}{4} \) and the fact that when \( (u - k)_+ \) is not zero, then

\[
u > k = \mu^+ - \frac{\omega}{2s} > \mu^+ - \frac{\omega}{2} = \frac{\omega}{2} > \frac{\omega}{4} ,
\]

since \( s \geq s_1 > 1 \), and therefore

\[
1 \geq u^{\gamma(x,t)} \geq \left( \frac{\omega}{4} \right)^{\gamma^+} = \frac{1}{a_0} .
\]
We then have
\[
\frac{1}{2a_0} \int \int_{Q(\frac{\nu_0}{2}a_0R^2, R)} \left| \nabla (u - k) \right|^2 dx \leq \left( \frac{\omega}{2^s} \right)^2 \frac{1}{R^2} \left( \frac{1}{\nu_0} a_0 + 2 \right) \int \int_{Q(\nu_0a_0R^2, 2R)} \chi_{[u > k]}
\]
\[
\leq \left( \frac{\omega}{2^s} \right)^2 \frac{1}{R^2} \left( \frac{1}{\nu_0} a_0 + 2 \right) 2^{N+1} \left| Q \left( \frac{\nu_0}{2}a_0R^2, R \right) \right|
\]
and consequently, multiplying by $2a_0$,
\[
\int \int_{Q(\frac{\nu_0}{2}a_0R^2, R)} \left| \nabla (u - k) \right|^2 dx \leq \left( \frac{\omega}{2^s} \right)^2 \frac{1}{R^2} \frac{4}{\nu_0} + 4a_0 \right) 2^{N+1} \left| Q \left( \frac{\nu_0}{2}a_0R^2, R \right) \right|
\]
\[
= \frac{2^{N+3}}{\nu_0} \left( \frac{\omega}{2^s} \right)^2 \frac{1}{R^2} \left( 1 + a_0\nu_0 \right) \left| Q \left( \frac{\nu_0}{2}a_0R^2, R \right) \right|
\]
\[
\leq \frac{C(M, N, \gamma^+)}{\omega^{(1+\gamma^+)(N+2)}} \left( \frac{\omega}{2^s} \right)^2 \frac{1}{R^2} \left| Q \left( \frac{\nu_0}{2}a_0R^2, R \right) \right| ,
\]
recalling the definition of $\nu_0$ given by (11).

Now we consider the levels $l = \mu + \frac{\omega}{2^{s+1}} > k = \mu + \frac{\omega}{2^s}$, $s = s_1, \ldots, s_2 - 1$, and define, for $t \in \left( -\frac{\nu_0}{2}a_0R^2, 0 \right)$,
\[
A_s(t) \equiv \left\{ x \in K_R : u(x, t) > \mu + \frac{\omega}{2^s} \right\}
\]
and
\[
A_s \equiv \int_{-\frac{\nu_0}{2}a_0R^2}^0 |A_s(t)| dt .
\]

Using Lemma 2.2 of [4, page 5] applied to the function $u(\cdot, t)$ for all times $t \in \left( -\frac{\nu_0}{2}a_0R^2, 0 \right)$, we get
\[
\left( \frac{\omega}{2^{s+1}} \right) |A_{s+1}(t)| \leq C(N) \frac{R^{N+1}}{|K_R \setminus A_s(t)|} \int_{[k < u < l]} |\nabla u| .
\]
Since $\mu + \frac{\omega}{2^s} \geq \mu + \frac{\omega}{2^{s+1}}$, for $s \geq s_1$,
\[
|A_s(t)| \leq |A_{s_1}(t)| < \left( 1 - \left( \frac{\nu_0}{2} \right)^2 \right) |K_R| , \quad \forall t \in \left( -\frac{\nu_0}{2}a_0R^2, 0 \right) ,
\]
by virtue of (16). Then, for all $t \in \left( -\frac{\nu_0}{2}a_0R^2, 0 \right)$,
\[
\left( \frac{\omega}{2^{s+1}} \right) |A_{s+1}(t)| \leq \frac{C(N)}{\nu_0^2} R \int_{[k < u < l]} |\nabla u| .
\]
and finally, integrating in time over \((-\frac{\nu}{2}a_0R^2,0)\) and using Hölder’s inequality, we arrive at

\[
\left(\frac{\omega}{2^{s+1}}\right) A_{s+1} \leq \frac{C(N)}{\nu_0^2} R \int_{-\frac{\nu}{2}a_0R^2}^0 \int_{[k<u<l]} |\nabla u| \\
\leq \frac{C(N)}{\nu_0^2} R \left( \int \int_{Q\left(\frac{\nu_0}{2}a_0R^2, R\right)} |\nabla (u-k)|^2 \right)^{\frac{1}{2}} \left| A_s \setminus A_{s+1} \right|^{\frac{3}{2}}.
\]

According to the previous energy estimates we get, for \(s = s_1, \ldots, s_2 - 1\),

\[
A_{s+1}^2 \leq \frac{C(M, N, \gamma^+)}{\omega_2^2(1+\gamma^+)(N+2)} \left| Q \left(\frac{\nu_0}{2}a_0R^2, R\right) \right| \left| A_s \setminus A_{s+1} \right|
\]

and we then add these inequalities for \(s = s_1, \ldots, s_2 - 1\).

Since \(\mu^+ - \frac{\omega}{2^{s+1}} \leq \mu^+ - \frac{\omega}{2^{s_2}},\ A_{s+1} \geq A_{s_2}\), and therefore

\[
\sum_{s=s_1}^{s_2-1} A_{s+1}^2 \geq (s_2 - s_1) A_{s_2}^2.
\]

Note also that \(\sum_{s=s_1}^{s_2-1} \left| A_s \setminus A_{s+1} \right| \leq \left| Q \left(\frac{\nu_0}{2}a_0R^2, R\right) \right|\). Collecting results, we arrive at

\[
A_{s_2}^2 \leq \frac{C(M, N, \gamma^+)}{\omega_2^2(1+\gamma^+)(N+2)(s_2 - s_1)} \left| Q \left(\frac{\nu_0}{2}a_0R^2, R\right) \right|^2
\]

and the proof is complete if we choose \(s_1 < s_2 \in \mathbb{N}\) sufficiently large so that

\[
\frac{C(M, N, \gamma^+)}{\omega_2^2(1+\gamma^+)(N+2)(s_2 - s_1)} \leq \nu^2.
\]

\[\square\]

**Remark 4.** It is clear from the indicated choice of \(s_2\) that it depends on \(\omega\).

**Lemma 4.** The number \(\nu \in (0,1)\) can be chosen (and consequently, so can \(s_2\)) such that

\[
u(x,t) \leq \mu^+ - \frac{\omega}{2^{s_2+1}}, \quad \text{a.e. } (x,t) \in Q \left(\frac{\nu_0}{2}a_0 \left(\frac{R}{2}\right)^2, \frac{R}{2}\right).
\]
Proof. Define two sequences of positive real numbers

\[ R_n = \frac{R}{2} + \frac{R}{2^{n+1}}, \quad k_n = \mu^+ - \frac{\omega}{2^{s_2+1}} - \frac{\omega}{2^{s_2+1+n}}, \quad n = 0, 1, 2, \ldots \]

and construct the family of nested and shrinking cylinders

\[ Q_n = Q\left(\frac{\nu_0}{2}a_0 R^2_n, R_n\right). \]

Consider the function \( u_\omega = \min\{u, \mu^+ - \frac{\omega}{2^{s_2+1}}\} \) and, in the weak formulation (3), take \( \phi = (u_\omega - k_n) + \xi_n^2 \), where \( 0 \leq \xi_n \leq 1 \) are smooth cutoff functions defined in \( Q_n \) and verifying

\[
\begin{cases}
\xi_n \equiv 1 \text{ in } Q_{n+1}, & \xi_n \equiv 0 \text{ on } \partial_p Q_n; \\
|\nabla \xi_n| \leq \frac{2^{n+2}}{R}, & |\Delta \xi_n| \leq \frac{2^{2(n+2)}}{R^2}, & 0 < \partial_t \xi_n \leq \frac{2^{2(n+2)}}{2^2 a_0 R^2},
\end{cases}
\]

where \( \partial_p Q_n \) denotes the parabolic boundary of \( Q_n \).

Then, for \( t \in (-\frac{\nu_0}{2}a_0 R^2_n, 0) \), we have formally (again, to be rigorous we would have to argue with the Steklov averages and pass to the limit in \( h \))

\[
0 = \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} \partial_t u \left((u_\omega - k_n) + \xi_n^2\right) \\
+ \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} u^{\gamma(x,t)} \nabla u \cdot \nabla \left((u_\omega - k_n) + \xi_n^2\right) := I_1 + I_2.
\]

Observe that

\[
I_1 = \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} \partial_t u \left((u_\omega - k_n) + \xi_n^2\right) \chi_{[u_\omega = u]}
\]

\[
+ \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} \partial_t u \left((u_\omega - k_n) + \xi_n^2\right) \chi_{[u_\omega = \mu^+ - \frac{\omega}{2^{s_2+1}}]}
\]

\[
= \frac{1}{2} \int_{K_{R_n} \times \{t\}} (u_\omega - k_n)^2 + \xi_n^2 - \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} (u_\omega - k_n)^2 \partial_t \xi_n \xi_n
\]

\[
+ \left(\frac{\omega}{2^{s_2+1+n}}\right) \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} \partial_t \left(u - \left(\mu^+ - \frac{\omega}{2^{s_2+1}}\right)\right) + \xi_n^2
\]

\[
\geq \frac{1}{2} \int_{K_{R_n} \times \{t\}} (u_\omega - k_n)^2 + \xi_n^2 - 3 \left(\frac{\omega}{2^{s_2+1}}\right)^2 \frac{2^{2(n+2)}}{a_0 R^2} \int_{-\frac{\nu_0}{2}a_0 R^2_n}^{t} \int_{K_{R_n}} \chi_{[u_\omega > k_n]},
\]
arguing as in the proof of Proposition 2 (with the obvious changes). Concerning $I_2$, we have

$$I_2 = \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} u_{\gamma(x,t)} \nabla u \cdot \nabla \left( (u_\omega - k_n) + \xi_n^2 \right) \chi_{[u_\omega = u]}$$

$$+ \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} u_{\gamma(x,t)} \nabla u \cdot \nabla \left( (u_\omega - k_n) + \xi_n^2 \right) \chi_{[u_\omega = u_\omega - \frac{\omega}{2s_2 + 1}]}$$

$$\geq \frac{1}{2} \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} u_{\omega(x,t)} |\nabla (u_\omega - k_n) + |\xi_n^2|$$

$$- 2 \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} u_{\omega(x,t)} (u_\omega - k_n)^2 |\nabla \xi_n|^2$$

$$- 2 \left( \frac{\omega}{2s_2 + 1} \right) \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{\mu_+ - \frac{\omega}{2s_2 + 1}}^{u} s_{\gamma(x,t)} \ ds \right)$$

$$\left( |\Delta \xi_n| + |\nabla \xi_n|^2 \right) \chi_{[u_\omega \geq u_\omega - \frac{\omega}{2s_2 + 1}]}$$

$$- \left( \frac{\omega}{2s_2 + 1} \right) \int_{-\frac{\nu}{2} a_0 R_n^2}^{t} \int_{K_{R_n}} \left( \int_{\mu_+ - \frac{\omega}{2s_2 + 1}}^{u} s_{\gamma(x,t)} (-\ln s) \ ds \right)$$

$$\left( |\nabla \gamma|^2 + |\nabla \xi_n|^2 \right) \chi_{[u_\omega \geq u_\omega - \frac{\omega}{2s_2 + 1}]}$$

using Cauchy's inequality and integration by parts.

Noting that, when $k_n < u = u_\omega < \mu_+ - \frac{\omega}{2s_2 + 1} < 1$,

$$\frac{\omega}{4} < \frac{\omega}{2} = \mu_+ - \frac{\omega}{2} < \mu_+ - \frac{\omega}{2s_1} < \mu_+ - \frac{\omega}{2s_2} < k_n < u_\omega \leq 1$$

(since $1 < s_1 < s_2$) and then

$$\frac{1}{a_0} \leq u_{\omega(x,t)} \leq 1 \quad \text{and} \quad (u_\omega - k_n)_+ \leq \frac{\omega}{2s_2 + 1} ;$$

when $u \geq \mu_+ - \frac{\omega}{2s_2 + 1}$

$$u_\omega = \mu_+ - \frac{\omega}{2s_2 + 1} \geq k_n ;$$

and also that

$$\int_{\mu_+ - \frac{\omega}{2s_2 + 1}}^{u} s_{\gamma(x,t)} \ ds \leq \frac{\omega}{2s_2 + 1}$$
and

\[ \int_{\mu^+-\frac{\omega}{2s^2+1}}^u s^{\gamma(x,t)}(-\ln s) \, ds \leq \int_{\mu^+-\frac{\omega}{2s^2+1}}^u (-\ln s) \, ds \]

\[ \leq \left( \frac{\omega}{2s^2+1} \right) \left( 1 - \ln \left( \mu^+ - \frac{\omega}{2s^2+1} \right) \right) \]

\[ \leq \left( \frac{\omega}{2s^2+1} \right) \frac{2}{\omega} \]

(since, as \( s_2 > s_1 > 1, \mu^+ - \frac{\omega}{2s^2+1} > \mu^+ - \frac{\omega}{2s_1^2} > \mu^+ - \frac{\omega}{2} = \frac{\omega}{2} \)), we obtain, with a reasoning similar to the one employed in the proof of Proposition 2, the estimate

\[ \sup_{-\frac{\nu_0}{2}a_0R_n^2 < t < 0} \int_{K_{R_n} \times \{ t \}} (u_\omega - k_n)^2 \xi_n^2 + \frac{1}{a_0} \int_{Q_n} |\nabla (u_\omega - k_n)_+|^2 \xi_n^2 \]

\[ \leq \left( \frac{\omega}{2s^2+1} \right) ^2 \frac{2 \cdot 2^{2(n+2)}}{R^2} \left\{ \frac{6}{\nu_0 a_0} + \frac{C(M)}{\omega} \right\} \int_{Q_n} \chi[\omega \geq k_n] . \]

Introducing the change of variables

\[ z = \frac{t}{\nu_0 a_0} \]

and defining the new functions

\[ \bar{u}_\omega(x,z) = u_\omega(x,\frac{\nu_0}{2}a_0z) , \quad \bar{\xi}_n(x,z) = \xi_n(x,\frac{\nu_0}{2}a_0z) , \]

the previous estimate reads

\[ \sup_{-R_n^2 < z < 0} \int_{K_{R_n} \times \{ z \}} (\bar{u}_\omega - k_n)^2 \bar{\xi}_n^2 + \frac{\nu_0}{2} \int_{Q(R_n^2,R_n)} |\nabla (\bar{u}_\omega - k_n)_+|^2 \bar{\xi}_n^2 \]

\[ \leq \left( \frac{\omega}{2s^2+1} \right) ^2 \frac{2 \cdot 2^{2(n+2)}}{R^2} \left\{ 6 + \frac{C(M)}{\omega} \nu_0 a_0 \right\} \int_{Q(R_n^2,R_n)} \chi[\bar{u}_\omega \geq k_n] . \]

Multiplying the above estimate by \( \frac{2}{\nu_0} \geq 1 \), we arrive at

\[ \| (\bar{u}_\omega - k_n)_+ \|_{V^2(Q(R_n^2,R_n+1))} \leq C(M) \left( \frac{\omega}{2s^2+1} \right) ^2 \frac{2 \cdot 2^{2(n+2)}}{R^2} \left\{ \frac{1}{\nu_0} + \frac{a_0}{\omega} \right\} A_n \]

\[ \leq \frac{C(M, N, \gamma^+)}{\omega^{(1+\gamma^+)(\frac{N}{2s^2+1})}} \left( \frac{\omega}{2s^2+1} \right) ^2 \frac{2 \cdot 2^{2(n+2)}}{R^2} A_n , \]
where $A_n$ is defined as

$$A_n \equiv \int_{-R_n^2}^{0} \int_{K_{R_n}} \chi[\bar{u}_n \geq k_n] \cdot$$

Observing that, on the one hand

$$\int \int_{Q(R_{n+1}^2, R_{n+1})} (\bar{u}_n - k_n)^2 \geq (k_{n+1} - k_n)^2 A_{n+1} = \left( \frac{\omega}{2^{n+1}} \right)^2 \frac{1}{2^{2(n+1)}} A_{n+1}$$

and, on the other hand, using Corollary 3.1 of [4, page 9],

$$\int \int_{Q(R_{n+1}^2, R_{n+1})} (\bar{u}_n - k_n)^2 \leq C(N) A_n^{\frac{2}{N+2}} \| (\bar{u} - k_n) \|_{V^2(Q(R_{n+1}^2, R_{n+1}))}^2,$$

we obtain

$$A_{n+1} \leq \frac{C(M, N, \gamma^+)}{\omega^{(1+\gamma^+)(N+2)}} \frac{2^{4n}}{R^2} A_n^{1+\frac{2}{N+2}}.$$

Defining $Y_n \equiv \frac{A_n}{|Q(R_{n+1}^2, R_{n+1})|}$ and noting that $\frac{|Q(R_{n+1}^2, R_{n+1})|^{1+\frac{2}{N+2}}}{|Q(R_{n+1}^2, R_{n+1})|} \leq 2^{N+4} R^2$, we get the algebraic inequality

$$Y_{n+1} \leq \frac{C(M, N, \gamma^+)}{\omega^{(1+\gamma^+)(N+2)}} \frac{2^{4n}}{R^2} Y_n^{1+\frac{2}{N+2}}.$$

Using a well known result on the fast geometric convergence of sequences, namely Lemma 4.1 of [4, page 12], the result is proved if we can assure that

$$Y_0 \leq C(M, N, \gamma^+) \frac{\omega^{(1+\gamma^+)(N+2)^2}}{2^{-(N+2)^2}},$$

which implies $Y_0 \leq \nu$. Then we can conclude that $Y_n \to 0$ when $n \to \infty$, and the result follows.

\begin{flushright}
\textbf{Proposition 3.}\ There exist positive numbers $\nu_0, \sigma_1 \in (0, 1)$, depending on the data and on $\omega$, such that, if (8) holds true then

$$\text{ess osc}_{Q\left(\frac{R^2}{a_0}, R\right)} u \leq \sigma_1 \omega.$$  \hfill (17)
\end{flushright}
Proof. The proof is trivial and similar to the proof of Corollary 1. We have
\( \sigma_1 = 1 - \frac{1}{2^{s_2+1}} \).

Proof of Proposition 1. Recalling the conclusions of Corollary 1 and Proposition 3, we take
\[ \sigma = \max \{ \sigma_0, \sigma_1 \} = \sigma_1, \]
since \( \sigma_0 = 1 - \frac{1}{4} < 1 - \frac{1}{2^{s_2+1}} = \sigma_1 \), because \( s_2 > 1 \). As \( \nu_0 \in (0,1) \)
\[ Q \left( \frac{\nu_0}{2} a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2} \right) \subset Q \left( a_0 \left( \frac{R}{2} \right)^2, \frac{R}{2} \right) \]
and the result follows.
