Abstract – 5,5'-Diethyl- and 5-phenyldipyrromethanes participate in cycloadditions with azo- and nitrosoalkenes giving dipyrromethanes with side chains containing open chain oximes and hydrazones. Controlling reaction stoichiometry it is possible to get mono or 1,9-dissubstituted derivatives. The reported methodology gave access to a range of dipyrromethanes with good structural features for various applications. It was demonstrated that reduction of dipyrromethanes containing α-oximino ester groups opens the way to new α-amino esters.

Keywords: Dipyrromethanes, Azoalkenes, Nitrosoalkenes, Hetero-Diels-Alder Reaction.

Dipyrrolic compounds are of wide interest as building blocks in organic synthesis, namely in the synthesis of porphyrins and porphyrin analogues such as meso-substituted corroles, chlorins, expanded porphyrins, and calix[4]pyrroles. On the other hand, dipyrromethanes are the precursors of BODIPY dyes (4,4-difluoro-4-bora-3a,4a-diaza-s-indacenes) whose photophysical properties make them the ideal fluorescent scaffold for the development of high performance imaging probes. Radioactive technetium complexes also have widespread application in molecular imaging. Thus, we envisioned that the synthesis of dipyrromethanes with structural requirements to act as Technetium (99m-Tc) ligands for application as radiotracers in cancer detection would be of particular interest. Functionalized dipyrromethanes are also potentially attractive structures for the development of new optical anion sensors, for application in biological systems and in the settling of environmental problems. In fact, pyrrole based anion receptors, including dipyrromethane derivatives, have been shown to be selective and efficient receptors for a variety of anionic species.

In this context, we decided to explore the hetero-Diels-Alder reaction of azoalkenes and nitrosoalkenes to achieve the functionalization of dipyrromethane derivatives. Cycloadditions of these heterodienes has been explored as a route to tetrahydro-1,2-oxazine, tetrahydro-pyridazine, open chain oxime and hydrazone derivatives. Our previous studies on hetero-Diels-Alder reactions of 3-tetrazolyl nitrosoalkenes and 3-tetrazolyl-1,2-diaza-1,3-butadienes demonstrated that it is an efficient approach for the synthesis of functionalized 5-(substituted)-1H-tetrazoles. Using pyrrole as the 2π component, open chain oximes and hydrazones are obtained. We envisaged that a diversity of dipyrromethanes might be produced through hetero-Diels-Alder reaction with azoalkenes and nitrosoalkenes, using 5,5'-di-substituted- and 5-mono-substituted...
dipyrromethanes as $2\pi$ components. On the other hand, the possibility of controlling mono- or di-functionalization would lead to a wider range of dipyrromethane derivatives allowing the diversification of potential applications. In this communication, details of this new synthetic strategy for the introduction of side-chains in positions 1 and 9 of dipyrromethanes via hetero-Diels-Alder reaction are presented (Scheme 1).

Scheme 1. Synthetic strategy for the functionalization of dipyrromethanes.

The heterodienes selected to carry out this study were generated in situ through base mediated dehydrohalogenation of $\alpha$-halohyrazones 2 or $\alpha$-haloxime 4. These azo- and nitrosoalkene precursors were obtained from the reaction of the corresponding hydrazine with $\alpha$-halo carbonyl compounds 1 and from the condensation of hydroxylamine with ethyl bromopyruvate (3), respectively (Scheme 2).\(^\text{12}\)

Scheme 2. Synthesis of azo- and nitrosoalkene precursors.

Initially, the behaviour of 5,5’-diethyldipyrromethane (6) towards 1,2-diaza-1,3-butadienes was explored (Scheme 3). Dipyrromethane 6 was prepared by a known synthetic methodology involving the acid-catalyzed condensation of 3-pentanone with pyrrole in aqueous medium.\(^\text{16}\) By treatment with sodium carbonate in dichloromethane at room temperature, hydrazones 2 were converted into the transient 1,2-diaza-1,3-
butadienes 5 which were trapped *in situ* by dipyrromethane 6 affording the corresponding open chain hydrazones 7 and 8. Carrying out the reaction using an excess of pyrromethane 6 (2.25 equiv.) the mono-functionalized derivative 8 could be isolated in moderate yield as single product whereas the reaction using a slight excess of hydrazones 2 afforded the di-functionalized pyrromethanes 7 in good yield. These reactions can be regarded as “formal” alkylation reactions, which are the result of hetero-Diels-Alder reactions followed by 1,4,5,6-tetrahydropyridazine ring opening via a 1,5-sigmatropic rearrangement and finally a enolization-type step, as previously observed in the reaction of 1,2-diaza-1,3-butadienes with heterocycles possessing high aromatic character such as pyrrole and indole.

Scheme 3. Hetero-Diels-Alder reaction of 5,5′-diethylpyrromethane (6) with 1,2-diaza-1,3-butadienes.

The work was extended to the cycloaddition of a 5-mono-substituted dipyrromethane with 1,2-diaza-1,3-butadiene 5a (Scheme 4). The TFA catalyzed condensation of benzaldehyde with neat excess of pyrrole afforded 5-phenyldipyrromethane (9), as reported by Lindsey *et al.* We were pleased to observed that the conversion of dipyrromethane 9 into 1,9-disubstituted dipyrromethane 10 showed similar efficiency to the one observed in the cycloaddition of 5,5′-diethylpyrromethane (6) with the same diene. In fact, dipyrromethane 10 was obtained in 56% yield. Using an excess of 5-phenyldipyrromethane (9) the mono-functionalized derivative 11 could be obtained in 31% yield.
Scheme 4. Hetero-Diels-Alder reaction of 5-phenyldipyrromethane (9) with 1,2-diaza-1,3-butadiene 5a.

We have also explored the hetero-Diels–Alder reaction of nitrosoalkene 12, generated in situ from the corresponding bromooxime 4, with dipyrromethane 6 (Scheme 5). In this case, it was observed that carrying out the mono-functionalization to give 13, followed by the subsequent cycloaddition leading to the target compound 14, was more efficient than a one-pot procedure. In fact, the latter led to a more difficult isolation since the formation of derivative 13 was also observed. Under the optimized reaction conditions dipyrromethane 13 was isolated in 59% yield and di-functionalized derivative 14 was obtained from 13 in 48% yield. It is noteworthy that compounds 13 and 14 have the structural requirements to act as Technetium (99mTc) ligands for application in cancer radioimaging.

Scheme 5. Hetero-Diels-Alder reaction of 5,5'-diethylidipyrromethane (6) with nitrosoalkene 12.

The reaction of nitrosoalkene 12 with 5-phenyldipyrromethane (9) was not as straightforward as with the 5,5'-diethylidipyrromethane (6), which prompted us to prepare dipyrromethane 17 using different strategies (Scheme 6). The hetero-Diels–
Alder reaction requires long reaction times leading to oxidation of the dipyromethanes making the isolation of the target compounds harder. The one-pot approach afforded the di-functionalized dipyromethane 17 in 19% yield. Reacting oxime 4 with an excess of 5-phenyldipyromethane (9) in the presence of sodium carbonate led to the formation of dipyromethane 16 in 42% yield. This heterocyclic compound, when subjected to another cycloaddition with nitrosoalkene 12, gave compound 17 in moderate yield (34%). Finally, an alternative strategy was devised. Dipyromethane 17 was obtained in 18% yield from the condensation of benzaldehyde with two equivalents of pyrrole 15 in dichloromethane, in the presence of a catalytic amount of TFA, a general procedure described by Lindsey et al.  

The functionalities introduced on the dipyromethane nucleus can be used for other useful transformations, as in the case of the reduction of α-oximino ester to α-amino esters. Therefore, the reduction of α-oximino ester 13 was carry out using aluminum amalgam in aqueous THF giving the corresponding α-amino ester which underwent N-protection with di-tert-butyl dicarbonate to afford compound 18 in 67% overall yield (Scheme 7).

A new synthetic strategy for the introduction of side-chains in positions 1 and 9 of dipyrrromethanes via hetero-Diels-Alder reaction with azo- and nitrosoalkenes is reported. This allowed the synthesis of new 5,5'-diethyl- and 5-phenyl dipyrromethanes functionalized with side chains containing open chain oximes and hydrazones. Furthermore, it was demonstrated that reduction of dipyrrromethanes containing α-oximino ester groups opens the way to new α-amino esters.

The new dipyrrromethanes have good structural features for various applications, namely for the synthesis of BODIPY dyes and Technetium ($^{99m}$Tc) ligands to be used as radiotracers, the synthesis of porphyrin analogues and the development of new optical anion sensors.

Acknowledgments
Thanks are due to Fundação para a Ciência e a Tecnologia (PEst-C/QUI/UI0313/2011 and SFRH/BD/61573/2009) for financial support. We acknowledge the Nuclear Magnetic Resonance Laboratory of the Coimbra Chemistry Center (www.nmrccc.uc.pt), University of Coimbra for obtaining the NMR data.

Supplementary Material
Experimental procedures and characterization data all new compounds. $^1$H and $^{13}$C NMR spectra for all new compounds. Supplementary data associated with this article can be found, in the online version, at XXX.
