## Determination of fumonisins B<sub>1</sub> and B<sub>2</sub> in Portuguese maize and maize-based samples by HPLC with fluorescence detection

Received: 18 November 2005 / Revised: 19 December 2005 / Accepted: 21 December 2005 / Published online: 8 February 2006  
© Springer-Verlag 2006

**Abstract** Fumonisins B<sub>1</sub> (FB<sub>1</sub>) and fumonisin B<sub>2</sub> (FB<sub>2</sub>) are the main members of a family of mycotoxins produced by *Fusarium verticillioides*, *Fusarium proliferatum*, and other fungi species of the section *Liseola*. The present work shows the results of comparative studies using two different procedures for the analysis of fumonisins in maize and maize-based samples. The studied analytical methods involve extraction with methanol/water, dilution with PBS, and clean-up through immunoaffinity columns. Two reagents (*o*-phthalaldehyde and naphthalene-2,3-dicarboxaldehyde) were studied for formation of fluorescent derivatives. The separation and identification were carried out by high-performance liquid chromatography with fluorescence detection. The optimized method for analysis of fumonisins in maize involved extraction with methanol/water (80:20), clean-up with an immunoaffinity column, and derivatization with naphthalene-2,3-dicarboxaldehyde (NDA). The limit of detection was 20 µg kg<sup>-1</sup> for FB<sub>1</sub> and 15 µg kg<sup>-1</sup> for FB<sub>2</sub>. Recoveries of FB<sub>1</sub> and FB<sub>2</sub> ranged from 79% to 99.6% for maize fortified at 150 µg kg<sup>-1</sup> and 200 µg kg<sup>-1</sup>, respectively, with within-day RSDs of 3.0 and 2.7%. The proposed method was applied to 31 samples, and the presence of fumonisins was found in 14 samples at concentrations ranging from 113 to 2,026 µg kg<sup>-1</sup>. The estimated daily intake of fumonisins was 0.14 µg kg<sup>-1</sup> body weight per day.

### Introduction

Fumonisins (FBs) are a group of toxins comprising fumonisins B<sub>1</sub> (FB<sub>1</sub>), B<sub>2</sub> (FB<sub>2</sub>), and B<sub>3</sub> (FB<sub>3</sub>). FBs are

structurally analogous to sphingosine [1] and are mainly yielded by *Fusarium verticillioides*, *Fusarium proliferatum*, and other fungi species of the section *Liseola* [2]. FB<sub>1</sub> is the most abundant and the most toxic fumonisin, followed by FB<sub>2</sub> [3]. FBs has been linked with an increased risk of oesophageal cancer in humans in the Transkei region of South Africa and China [1] and are possibly connected with neural tube defects (NTD) in South Texas, USA [4]. FB<sub>1</sub> is classified by International Agency for Research on Cancer (IARC) as possibly carcinogenic in humans (Group 2B) [5].

The wide geographical distribution of the fumonisin-producing maize pathogen *F. verticillioides* and its endophytic nature in maize have resulted in fumonisins occurring naturally in maize or products containing maize worldwide [6]. High levels of fumonisins in maize have been found in many countries, including Morocco [7], Brasil [8], Nigeria [9], and South Africa [10]. In Europe sporadic studies have been recently published [11].

Maize (*Zea mays* L.) is one of the most important crops in Portugal, representing a maize area and production of 126,000 ha and 665,000 Mt, respectively [12].

In Portugal, a single investigation of FB<sub>1</sub> and FB<sub>2</sub> in nine naturally contaminated maize hybrids, originating from the 1992 crop from the Agricultural School of Coimbra, was reported in international references, and revealed a high frequency of contamination, 100% [13].

Since the discovery of these mycotoxins and their characterization in 1988, there has been significant progress in the analytical methods used for their detection [14].

Recently, Lino et al. [15] reviewed the analytical methodology available for the determination of fumonisins in foods. These methods generally involve liquid extraction, with mixtures of polar solvents, such as methanol/water [16, 17], acetonitrile/water [18], methanol/acetonitrile/water [19], and acetonitrile/NaH<sub>2</sub>PO<sub>4</sub> [20]. A clean-up procedure is frequently applied that usually employs solid-phase extraction (SPE) columns such as with reversed-phase columns [18, 20], strong anion exchange columns (SAXs) [8, 21], and immunoaffinity columns (IACs) [17, 22] that present higher specificity. Different derivatization

reagents have been reported, namely, *o*-phthalaldehyde (OPA)—the most used [8, 9, 21], naphthalene-2,3-dicarboxaldehyde (NDA) [19, 20, 23], and 4-fluoro-7-nitrobenzofurazan (NBD-F) [24]. Detection and quantification have preferentially been performed using HPLC with fluorescence or mass spectrometry detection [8, 9, 21, 22, 25–28] although other chromatographic, electrophoretic, and immunological methods have been reported [15].

The objective in the present study was to optimize a sensitive and accurate method for determination of FBs in maize and derivatives by HPLC with pre-column derivatization and fluorescence detection, and to provide data on the occurrence of FB<sub>1</sub> and FB<sub>2</sub> in 31 maize and maize product samples consumed in central Portugal. The method was useful for assessing the potential contribution of dietary exposure to maize products in Portuguese consumers.

## Materials and methods

### Apparatus and chromatographic conditions

The high-performance liquid chromatography (HPLC) apparatus used consisted of a Gilson 307 pump (Gilson Medical Electronics, Villiers-le-Bel, France), one 50- $\mu$ L Rheodyne 7125 injector (Cotati, CA, USA), a 5- $\mu$ m C<sub>18</sub> Nucleosil 120 guard column KS (30 mm  $\times$  4-mm i.d.), and a 5- $\mu$ m C<sub>18</sub>Nucleosil 120 column (250 mm  $\times$  4.6-mm i.d.). A Perkin Elmer LS45 spectrofluorimeter (Perkin Elmer, Beaconsfield, UK) operating at an excitation wavelength of 420 nm and an emission wavelength of 500 nm was used.

The results were recorded on a 3990 integrator (Hewlett-Packard, Philadelphia, PA). The mobile phase (acetonitrile/water/acetic acid 61:38:1 v/v/v) was maintained at a flow rate of 1 mL min<sup>-1</sup>.

Isocratic analysis under the conditions described above allowed the elution of FB<sub>1</sub> and FB<sub>2</sub> with a retention time of about 7.36 min and 13.34 min, respectively, when NDA derivatization was used.

A Meditronic S-599 centrifuge (Selecta, Barcelona, Spain), Retsh vortex mixer (Haan, Germany), and a Sonorex RK 100 ultrasonic bath (Berlin, Germany) were also used.

### Chemicals

HPLC-grade acetonitrile (ACN) and methanol were purchased from Carlo Erba (Milan, Italy). Acetic acid, hydrochloric acid, sodium hydroxide, potassium chloride, potassium dihydrogen phosphate, anhydrous disodium hydrogen phosphate, potassium cyanide, sodium tetraborate, and sodium chloride were obtained from Merck (Darmstadt, Germany). Water was prepared from a Milli Q system (Millipore, Bedford, MA, USA). FB<sub>1</sub> and FB<sub>2</sub> standards, naphthalene-2,3-dicarboxaldehyde (NDA), and 2-mercaptoethanol (MCE) were obtained from Sigma Chemicals Co (St. Louis, USA). *o*-Phthalaldehyde (OPA) was obtained from Carlo Erba (Milan, Italy).

FumoniTest immunoaffinity columns were from Vicam (Watertown, USA).

Phosphate buffer solution (PBS) was prepared from 0.2 g potassium chloride, 0.2 g potassium dihydrogen phosphate, 1.2 g anhydrous disodium hydrogen phosphate, and 8.0 g sodium chloride to 990 mL distilled water, adjusted to pH 7.0 with 25% HCl, and the solution was made up to 1 L.

The OPA derivatization reagent was prepared by mixing 40 mg OPA, 1 mL of methanol, 5 mL of a 0.1 M aqueous sodium tetraborate, and 50  $\mu$ L of 2-mercaptoethanol. The naphthalene-2,3-dicarboxaldehyde (NDA) solution was prepared at 0.5 mg mL<sup>-1</sup> in acetonitrile. The potassium cyanide was prepared at 0.13 mg mL<sup>-1</sup>; 0.05M sodium borate solution was adjusted to pH 9.5 with 1 N NaOH.

The mobile phase consisted of acetonitrile/water/acetic acid (61:38:1 v/v/v).

The stock solutions, prepared in the FB<sub>1</sub> and FB<sub>2</sub> vials purchased from Sigma Chemicals, were made in 1 mL acetonitrile/water (50:50) at 1,000  $\mu$ g mL<sup>-1</sup>. Intermediate solutions were prepared at 50  $\mu$ g mL<sup>-1</sup>, diluting 250  $\mu$ L of stock solution with 5 mL acetonitrile/water (50:50). For fortification assays, one work solution was prepared with acetonitrile/water (50:50) at 5  $\mu$ g mL<sup>-1</sup> for both fumonisins. For determination of the calibration curve, two work solutions were prepared at 50  $\mu$ g mL<sup>-1</sup> and 5  $\mu$ g mL<sup>-1</sup>. The others were prepared by diluting one of these solutions at the following concentrations: 5.0, 2.5, 1.0, 0.5, and 0.25  $\mu$ g mL<sup>-1</sup>. All solutions were kept in amber flasks to protect from light.

### Sampling

A total of 31 samples were purchased in commercially available sizes from March to July 2005 at shops, health food stores, and supermarkets located in the city of Coimbra. The following commodities were collected: yellow maize ( $n=9$ ), white maize ( $n=2$ ), maize flour ( $n=3$ ), maize semolina ( $n=3$ ), maize starch ( $n=3$ ), sweet maize ( $n=11$ ). Samples, except for maize flour, maize semolina, and maize starch, were finely milled in the switching apparatus.

### Recoveries

The recoveries of fumonisins from maize and maize starch were determined by spiking the ground sample of each food (three replications) with known amounts of fumonisins at final concentrations between 100  $\mu$ g kg<sup>-1</sup> and 250  $\mu$ g kg<sup>-1</sup>.

### Extraction and clean-up procedures

#### Method A

Ground samples (50 g) were mixed with 5 g NaCl and placed into a blender jar. One hundred mL CH<sub>3</sub>OH/H<sub>2</sub>O

**Fig. 1** Liquid chromatography spectrofluorimetric chromatogram of fumonisin B<sub>1</sub> and B<sub>2</sub> standard (a) (retention time 7.36 and 13.34 min for FB<sub>1</sub> and FB<sub>2</sub>, respectively), one fortified sample at 250  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 200  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub> (b), and one contaminated sample (c), obtained using the optimized method

(80:20 v/v) was added. The mixture was blended at high speed for 5 min, filtered through a Whatman N<sup>o</sup>1 filter paper, and collected in a clean vessel. Ten mL of filtered extract was transferred to another vessel and eluted with 40 mL PBS. The extract was filtered through microfiber filter (Whatman 934-AH, 110 mm). Ten mL was added to a FumoniTest IAC attached onto a vacuum manifold. The column was washed with 10 mL PBS, and fumonisins were eluted with 1.5 mL methanol. After evaporation under a gentle nitrogen stream at 60°C, the residue was redissolved in 50  $\mu\text{L}$  methanol/water (50:50 v/v).

#### Method B

Ground samples (25 g) were extracted with 40 mL CH<sub>3</sub>OH/H<sub>2</sub>O (80:20 v/v), centrifuged for 15 min at 2,500 g. The remaining solid was extracted twice with 30 mL each. The three extracts were combined and filtrated (Whatman N<sup>o</sup>1 paper). For clean-up, 10 mL of filtrate diluted with 40 mL phosphate-buffered saline was filtrated through glass microfiber. Twenty mL was added to a FumoniTest IAC attached onto a vacuum manifold. The column was washed with 10 mL PBS, and fumonisins were eluted with 2  $\times$  1.5 mL methanol. After evaporation under a gentle nitrogen stream at 60°C, the residue was reconstituted with 50  $\mu\text{L}$  methanol/water (50:50 v/v).

#### Derivatization

Five hundred microliter 0.05 M sodium borate buffer (pH 9.5 adjusted with 1 N NaOH), 500  $\mu\text{L}$  sodium cyanide reagent, and 150  $\mu\text{L}$  NDA reagent (0.5 mg mL<sup>-1</sup> ACN) were added to the reconstituted residue. The mixture was heated for 15 min at 60°C in a heating bath and cooled to room temperature.

## Results and discussion

The calibration curves were obtained using the linear least-squares regression procedure for the peak area plotted versus the concentration. The linearity for FB<sub>1</sub> and FB<sub>2</sub>, in the working standard solutions at four determinations of

**Table 1** Comparison of different chromatographic conditions with OPA at  $\lambda_{\text{exc}}=335$  nm and  $\lambda_{\text{em}}=440$  nm

Volumes of OPA ( $\mu\text{L}$ )	Quantity of standard (ng)	Mobile phase	Flow rate (mL min <sup>-1</sup> )

100	50	B=ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (59.0:40.0:1.0)	1.0

**Table 2** Comparison of different chromatographic conditions with NDA at  $\lambda_{\text{exc}}=420$  nm and  $\lambda_{\text{em}}=500$  nm

Mobile phase	Flow rate (mL min <sup>-1</sup> )
A = 65% ACN/CH <sub>3</sub> COOH (99:1) + 35% H <sub>2</sub> O/ CH <sub>3</sub> COOH (99:1)	1.0
B = ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (63:36:1)	1.0
C = ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (60:39:1)	1.0
D = ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (59:40:1)	0.9
E = ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (62:40:1)	1.0
F = ACN/H <sub>2</sub> O/CH <sub>3</sub> COOH (61:38:1)	1.0

five concentration levels, between 0.25 and 5.0  $\mu\text{g mL}^{-1}$ , which corresponds to 0.52 ng and 10.4 ng injected, was good as shown by the fact that the correlation coefficients ( $r^2$ ) were 0.984 and 0.994 for FB<sub>1</sub> and FB<sub>2</sub>, respectively.

Figure 1 shows the HPLC spectrofluorimeter chromatograms of the FBs standard, one sample and one sample fortified using method B. FB<sub>1</sub> and FB<sub>2</sub> standards were initially analyzed using pre-column derivatization with *o*-phthalaldehyde (OPA) and reversed-phase HPLC separation with an isocratic elution followed by fluorescence detection. Different chromatographic conditions were used (Table 1). When mobile phase A was used, according to Bittencourt et al. [8], long retention times were obtained: 12.57 for FB<sub>1</sub> and 33.10 for FB<sub>2</sub>. The proportion of acetonitrile was increased and the retention times decreased to 5.49 and 10.09 for FB<sub>1</sub> and FB<sub>2</sub>, respectively.

Several fluorescent derivatives have been reported. Although OPA-MCE is currently the most commonly used derivatization reagent it has the disadvantage of exhibiting time-dependent degradation, leading to the rapid decay of fluorescence after derivatization [29–31]. This disadvantage was overcome by the use of naphthalene-2,3-dicarboxaldehyde (NDA) that has been reported in several studies [19–21, 29, 32].

Derivatization reaction with NDA was performed according to the methods of Chu and Li [32] and Bennett and Richard [29], with some modifications. The best conditions were obtained using 150  $\mu\text{L}$  of derivatization reagent and replacing the redissolution of the residue by 50  $\mu\text{L}$  methanol/water (50:50). Different mobile phases were also experimented (see Table 2). The best results were obtained with ACN/H<sub>2</sub>O/CH<sub>3</sub>COOH (61:38:1 v/v/v).

NDA with KCN formed a highly fluorescent derivative which was relatively stable over 24 h [30].

Studies on the stability of NDA fluorescent derivatives were performed with the same standard, after 24 h and 8 days (Table 3). This study demonstrated that after 1 day, the stability of NDA-FB<sub>1</sub> and NDA-FB<sub>2</sub> decreased slightly. However, a minor increase in the percentage of NDA-FB<sub>1</sub> was observed, as reported by Bennett and Richard [29]. After 8 days, the loss of FB<sub>2</sub> was more significant than that of FB<sub>1</sub>. NDA-FBs derivatives have higher stability than OPA derivatives, as reported by Sydenham et al. [33] and Williams et al. [31]. NDA also tends to give higher values at lower toxin levels present in maize samples [32].

The methanol/water (80:20 v/v), previously applied by Cortez-Rocha et al. [17] used as an extraction solvent, was successfully used to extract fumonisins from maize and maize-based products.

The accuracy was determined by calculating the mean recovery values used for each fortification level (Table 4). The recovery values for FB<sub>1</sub>, using the method B, were 79.0% and 98.5% for fortification levels at 150 and 250  $\mu\text{g kg}^{-1}$ , respectively. For FB<sub>2</sub>, recovery values were 98.4% and 99.6% for fortification levels at 100 and 200  $\mu\text{g kg}^{-1}$ , respectively. The precision was calculated from intraday repeatability ( $n=3$ ) and interday repeatability (3 days). For FB<sub>1</sub>, the intraday repeatability obtained oscillated between 3.0 and 3.9% for fortification levels at 150 and 250  $\mu\text{g kg}^{-1}$ , respectively. For FB<sub>2</sub>, intraday repeatability was 2.7 and 10.4% at 200 and 100  $\mu\text{g kg}^{-1}$ , respectively. The 3-day repeatability ( $n=9$ ) obtained for FB<sub>1</sub>, oscillated between 10.0 and 14.0% for fortification levels at 150 and 250  $\mu\text{g kg}^{-1}$ , respectively. For FB<sub>2</sub> the corresponding values were 15.1 and 15.8% at 200 and 100  $\mu\text{g kg}^{-1}$ , respectively.

These values were lower, about 50%, using method A either with normal filtration [19, 22] or vacuum filtration. The filtration process therefore required modification, since the slurry produced after extraction clogged the Whatman N°1 filter paper, with or without vacuum, leading to losses. Due to the characteristics of the sample, an efficient process for separating the matrix residue from the solvent extract was essential. Centrifugation was crucial to improve this step [34]. Moreover, the time expended when method B was applied was much lower. The centrifugation step allowed good separation between sample residue and extraction solution when 2,500 g was applied in contrast to what happened with 500 g and 1,000 g. Attempts were made to optimize the analytical

**Table 3** Stability of NDA fluorescent derivatives (ng and %)

Fumonisin	1 day		1 day		8 days	
	ng	(%)	ng	(%)	ng	(%)
FB <sub>1</sub>	1.04	1.15	2.08	1.65	2.08	1.41
	(100)	(110)	(100)	(79.4)	(100)	(67.7)
FB <sub>2</sub>	1.04	0.66	2.08	1.56	2.08	0.67
	(100)	(62.9)	(100)	(75.0)	(100)	(32.1)

**Table 4** Accuracy and intra-assay validation results ( $n=3$ ) and inter-assay ( $n=9$ ) obtained with the optimized method

Fumonisin	Fortification level ( $\mu\text{g kg}^{-1}$ )	Recovery mean (%)	RSD	
			within-day (%)	between-day (%)
FB <sub>1</sub>	150	79.0	3.0	10.0
	250	98.5	3.9	14.0
FB <sub>2</sub>	100	98.4	10.4	15.8
	200	99.6	2.7	15.1

methodology. Extraction of 25 g of a contaminated sample, spiked with 100  $\mu\text{g kg}^{-1}$  of FB<sub>1</sub> and FB<sub>2</sub>, centrifuging twice using 50 mL of extraction solvent, resulted in recoveries of 61.5% for FB<sub>1</sub> and 95.6% for FB<sub>2</sub>. As the result obtained for FB<sub>1</sub> was low, centrifugation was tried three times, and FBs were eluted from IAC twice with 1.5 mL methanol.

The limit of detection obtained using the NDA derivatization procedure, at a signal-to-noise ratio of 3:1, was 20  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 15  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>.

### Application to real samples

The method B was successfully applied to 31 samples of maize and maize-based products, and the presence of FBs was verified in 14 samples (45%). The analyzed samples revealed high contamination levels, between nd and 1,569  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and between nd and 457  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>. In all groups of studied commodities, the mean concentration of FB<sub>2</sub> is lower than FB<sub>1</sub> (Table 5), which is usual in other studies [11, 35].

In our study, 67% of yellow maize and 100% of with maize samples (Table 5), which corresponds to 72.7% for all maize samples, were contaminated with FBs. These results are according to the only known study in Portugal for FB<sub>1</sub> and FB<sub>2</sub> in nine naturally contaminated maize hybrids, originating from the 1992 crop from the Agricultural School of Coimbra [13], which presented one incidence of 100%. The mean concentrations in the present study for the totality of maize samples were 329  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 131  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>, which are much lower when compared to the studies in Portuguese maize samples in 1992: 1,031  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 1,077  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub> [13].

White maize samples, used for the preparation of *cachupa*, a traditional dish from Cabo Verde, presented higher levels of both fumonisins than yellow samples, 638  $\mu\text{g kg}^{-1}$  versus 421  $\mu\text{g kg}^{-1}$ .

The average contamination levels found in maize samples, 329  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 131  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>, are lower than those reported in Spain (4,800  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 1,900  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>), UK (3,046  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 1,268  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>), and Morocco (1,930  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub>) [36, 35, 7]. However the percentage of positive samples in our study (72.7%) is similar to that reported in Spain (87.3%). In Nigeria similar levels of contamination have been reported (495  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 114  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>) [9].

Maize flour samples presented the highest mean concentration of FB<sub>1</sub> contamination, 822  $\mu\text{g kg}^{-1}$ . FB<sub>2</sub> presented a mean value of 173  $\mu\text{g kg}^{-1}$ . Higher values have been reported in France (1,113  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub>) [25], Italy (FB<sub>1</sub> ranged from 10 to 2,870  $\mu\text{g kg}^{-1}$  and FB<sub>2</sub> from 10 to 420  $\mu\text{g kg}^{-1}$ ) [26], and Brazil (2,100  $\mu\text{g kg}^{-1}$  for FB<sub>1</sub> and 700  $\mu\text{g kg}^{-1}$  for FB<sub>2</sub>) [8], whereas in Argentina the mean contamination of FB<sub>1</sub> and FB<sub>2</sub> were lower: 358  $\mu\text{g kg}^{-1}$  and 122  $\mu\text{g kg}^{-1}$ , respectively [37].

Results obtained for FB<sub>1</sub> (118  $\mu\text{g kg}^{-1}$ ) and FB<sub>2</sub> (nd) in maize semolina are in agreement with those reported by

**Table 5** Prevalence and levels of fumonisins in maize and maize products from Portugal

Maize semolina	3	2 (67)	2:0	nd-183	118	171	nd	-	-	nd-183	118	171
Maize starch	3	0 (0)	0:0	nd	-	-	nd	-	-	nd	-	-
Sweet maize	11	2 (18)	2:0	nd-523	64	0	nd	-	0	nd-523	64	0

Piñeiro et al. [38] in Uruguay ( $105 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and nd for  $\text{FB}_2$ ), Pittet et al. [39] in Switzerland ( $260 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and  $100 \mu\text{g kg}^{-1}$  for  $\text{FB}_2$ ), and Broggi et al. [37] in Argentina ( $135 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and  $39.1 \mu\text{g kg}^{-1}$  for  $\text{FB}_2$ ).

Fumonisin were not detected in maize starch. Piñeiro et al. [39] detected neither  $\text{FB}_1$  nor  $\text{FB}_2$  in the analyzed maize starch samples from Uruguay. This fact can be explained by the wet-milling process that leads to the migration of fumonisins into aqueous solutions during steeping [6].

Sweet maize samples presented the lowest contamination,  $64 \mu\text{g kg}^{-1}$  in 18% of the analyzed samples for  $\text{FB}_1$ , with no detection for  $\text{FB}_2$ . Low contamination levels were also reported by Truckess et al. [40]:  $70 \mu\text{g kg}^{-1}$  for canned maize and  $98 \mu\text{g kg}^{-1}$  for frozen maize; Pittet et al. [39] reported  $70 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and nd for  $\text{FB}_2$  in Switzerland; and Piñeiro et al. [38] reported  $65 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and nd for  $\text{FB}_2$ , in Uruguay.

The comparison between countries in Europe is somehow difficult regarding the few recent reports of contamination by fumonisins in these kinds of goods.

One maize flour sample exceeded the recommended limit of  $2,000 \mu\text{g kg}^{-1}$  proposed by the European Mycotoxin Awareness Network [41], and two maize samples exceeded the maximum allowable concentration of  $\text{FB}_1+\text{FB}_2$  established by Switzerland,  $1,000 \mu\text{g kg}^{-1}$  [42].

For maize samples and maize products collected in a central zone of Portugal, the average sample contamination of  $\text{FB}_1 + \text{FB}_2$  was  $303 \mu\text{g kg}^{-1}$ . Assuming that the estimation of average daily intake of maize in the Portuguese population is 27.9 g per person per day [43] and that an adult body weights 60 kg, the estimated daily intake (EDI) of fumonisins in this study was  $0.14 \mu\text{g kg}^{-1}$  body weight per day. These values are lower than the  $2 \mu\text{g kg}^{-1}$  established by Commission Regulation (EC) No 856/2005[44].

According to data from Portuguese Food Balance, maize consumption in 2003 reached 10.19 kg per person per year, which means 27.90 g per person per day, second place in the EU rank of total consumption of cereals [43]. Accepting this, the daily intake would reach, on average,  $0.14 \mu\text{g kg}^{-1}$  body weight per day or  $0.98 \mu\text{g kg}^{-1}$  body weight per week, a close value (70%) to the estimated total intake of  $\text{FB}_1$  in the European diet,  $1.4 \mu\text{g kg}^{-1}$  body weight per week [45]. The provisional maximum tolerable daily intake (PMTDI) for  $\text{FB}_1+\text{FB}_2$  is  $2 \mu\text{g kg}^{-1}$  body weight per day. This data was not overlapped for the most contaminated sample, representing 47.1% of the PMTDI reported by EMAN [41], but represents 118% when TDI of  $0.8 \mu\text{g kg}^{-1}$  body weight per day, proposed by Gelderblom et al. [46] is chosen as reference.

## Conclusions

Extraction with methanol/water, centrifugation, and dilution with PBS allows the supernatant to be applied onto an IAC column, making it possible to achieve low limits of detection. Stability of NDA fluorescent derivatives over-

whelmed the time-dependent degradation presented by OPA. This optimized analytical methodology provides good results in terms of accuracy, repeatability, intermediate precision and sensitivity, and has been shown to be reliable for determination of  $\text{FB}_1$  and  $\text{FB}_2$  in maize and maize products presenting limits of detection of  $20 \mu\text{g kg}^{-1}$  and  $15 \mu\text{g kg}^{-1}$  for  $\text{FB}_1$  and  $\text{FB}_2$ , respectively.

The application of the procedure to 31 samples from the central Portugal has demonstrated that 45% of the samples were contaminated,  $\text{FB}_1$  contamination levels were higher than  $\text{FB}_2$ , and some maize samples and maize flour exceed the recommended limits.

None of the analyzed samples exceeded the provisional maximum tolerable daily intake. The estimated daily intake demonstrated that FBs do not represent a real concern for consumers.
